

Caveat: Not Sunil Chandra's talk

– This talk will not be on a lepto-hadronic model, but will feature SEDs and cascade emission as Sunil's talk promised.

A PARAMETER STUDY OF THE HADRONIC SYNCHROTRON MIRROR MODEL ON 3C279

Laenita De Jonge

Supervisor: Markus Böttcher

15 December 2023

Aim - Questions to be answered

The motivation behind studying the orphan flares:

- What radiation mechanisms produce orphan TeV flares?
- Are protons accelerated to ultra-relativistic energies in the jets of blazars?
- Are hadronic interactions expected to be associated with the production of very-high-energy neutrinos?
- Why is the variability of 3C 279 sometimes correlated across the electromagnetic spectrum and sometimes not, as seen in other blazars as well?

The motivation behind the parameter study:

- To see how some of the different parameters influence the model.
- Try to minimize the required jet power.

What this presentation covers

- Background
 - SED components
 - Orphan Flares
- 3C 279 flare
- The hadronic synchrotron mirror model
 - Results
- Parameter study
- Summary and Future Work

SEDs

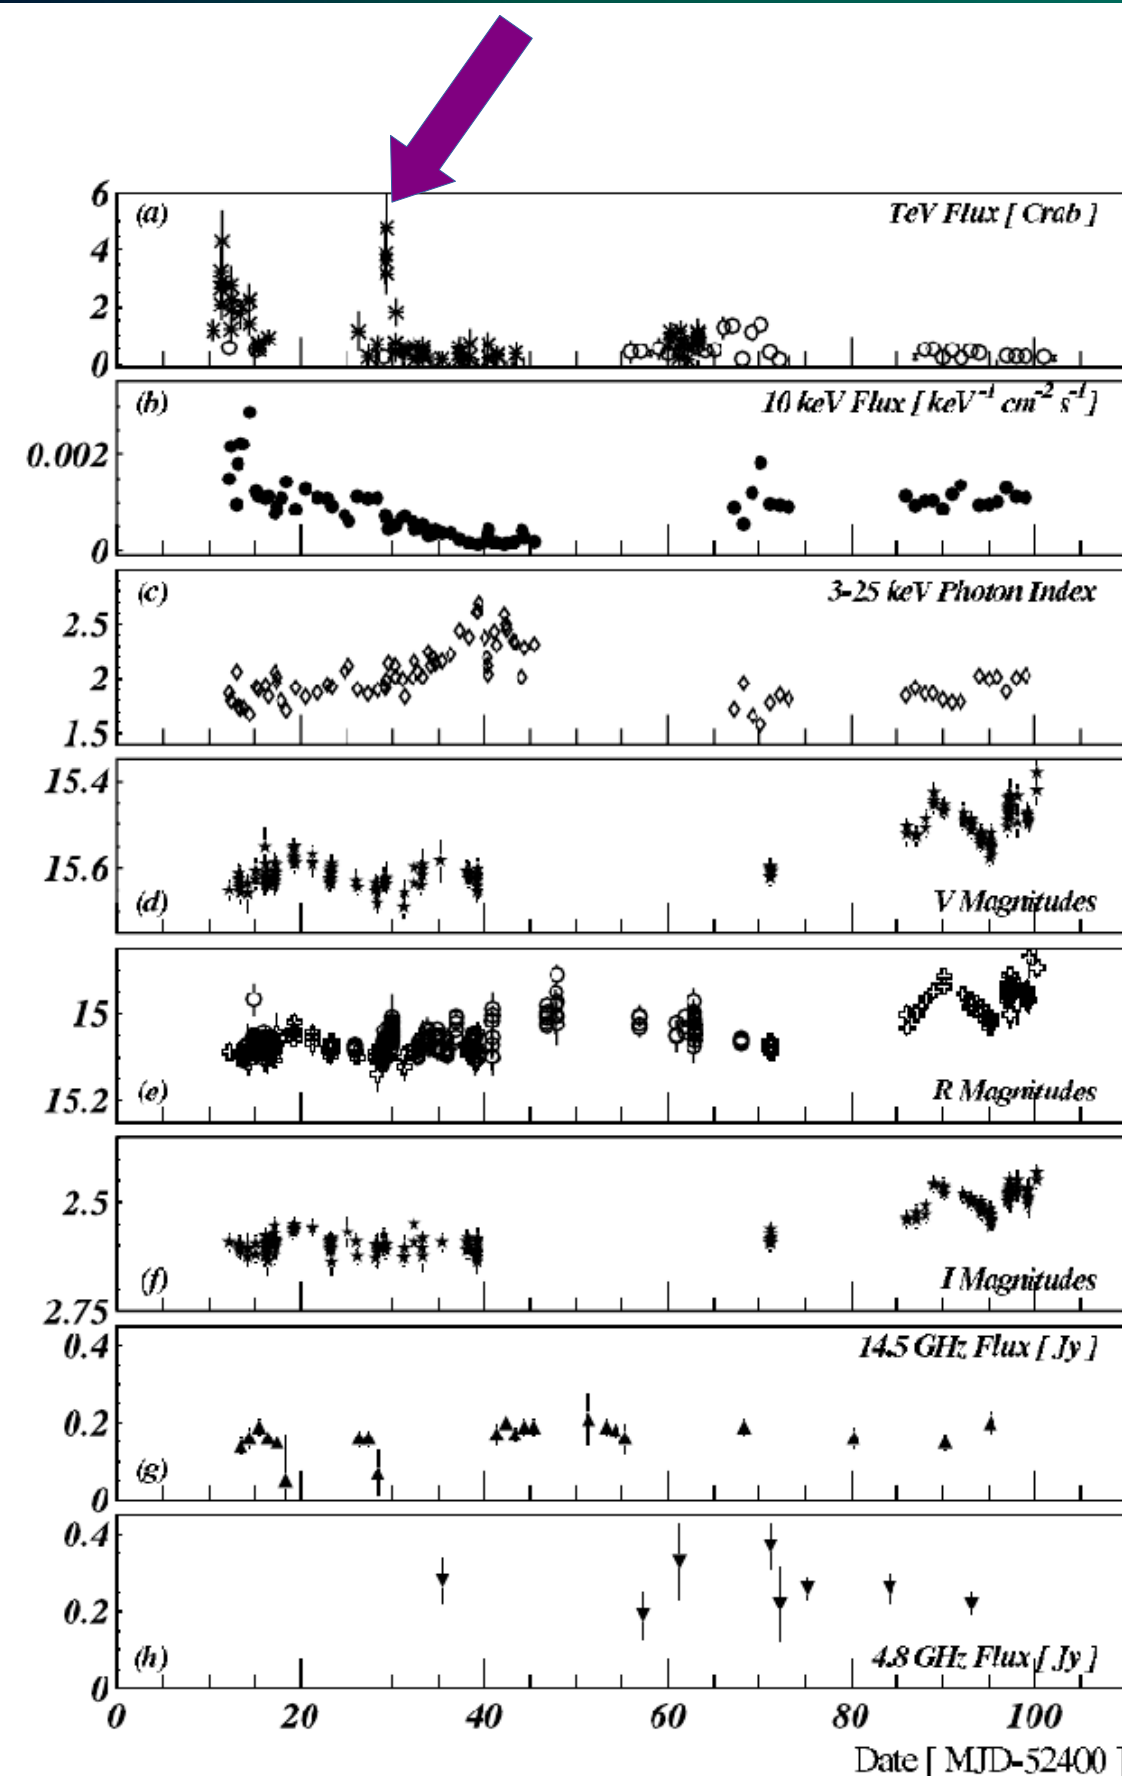

- SED's of blazars are characterised by two components
- First Component: Electron Synchrotron radiation
- Second Component: can be **leptonic** or **hadronic**:
 - Compton scattering
 - Proton synchrotron radiation
 - Photo-Pion Production

[BÖTTCHER ET AL., 2009]

Orphan Flares

- Extreme variability and flaring in different wavebands
- Flaring in one frequency band unaccompanied by flaring in other bands
- Orphan flares are usually secondary flares

[KRAWCZYNSKI ET AL., 2004]

3C 279 Flare

The Observed Orphan flare

Eleven days after a Fermi-LAT flare was observed with counterparts in the X-ray and optical bands, an orphan flare in the VHE γ -ray band was detected.

- 3C 279 is a FSRQ at a redshift of $z = 0.536$.
- 28th January 2018
- H.E.S.S. data in period bounded by the red lines.
- ToO observation was ongoing because of the Fermi-LAT flare by Fermi, HESS, Swift-XRT and ATOM.

[DMYTRIIEV, 2020]

Motivation for Hadronic scenario

Why we chose a hadronic mirror scenario:

- Leptonic SSC models predict quasi-simultaneous flaring in other wavebands like X-ray and optical bands.
- Matter in blazar jets might be dynamically dominated by baryon content [Sikora & Madejski, 2000].
- Inspired by [Böttcher, 2005] with application to orphan the flare of 1ES 1959+650.
- The mirror lowers the threshold of the proton energy required for photo-pion production.

Hadronic Synchrotron Mirror Model

Important Parameters

- The normalisation of the proton spectrum
- Magnetic field
- The Lorentz factor that signifies the break in the spectrum
- Radius of the cloud
- Fraction of reflected photons
- The Doppler factor

N_0	2.5×10^{37}
B	100 G
γ_b	9.8×10^7
R_{cl}	5.5×10^{15} cm
τ	0.001
δ	10

A list of the model parameters.

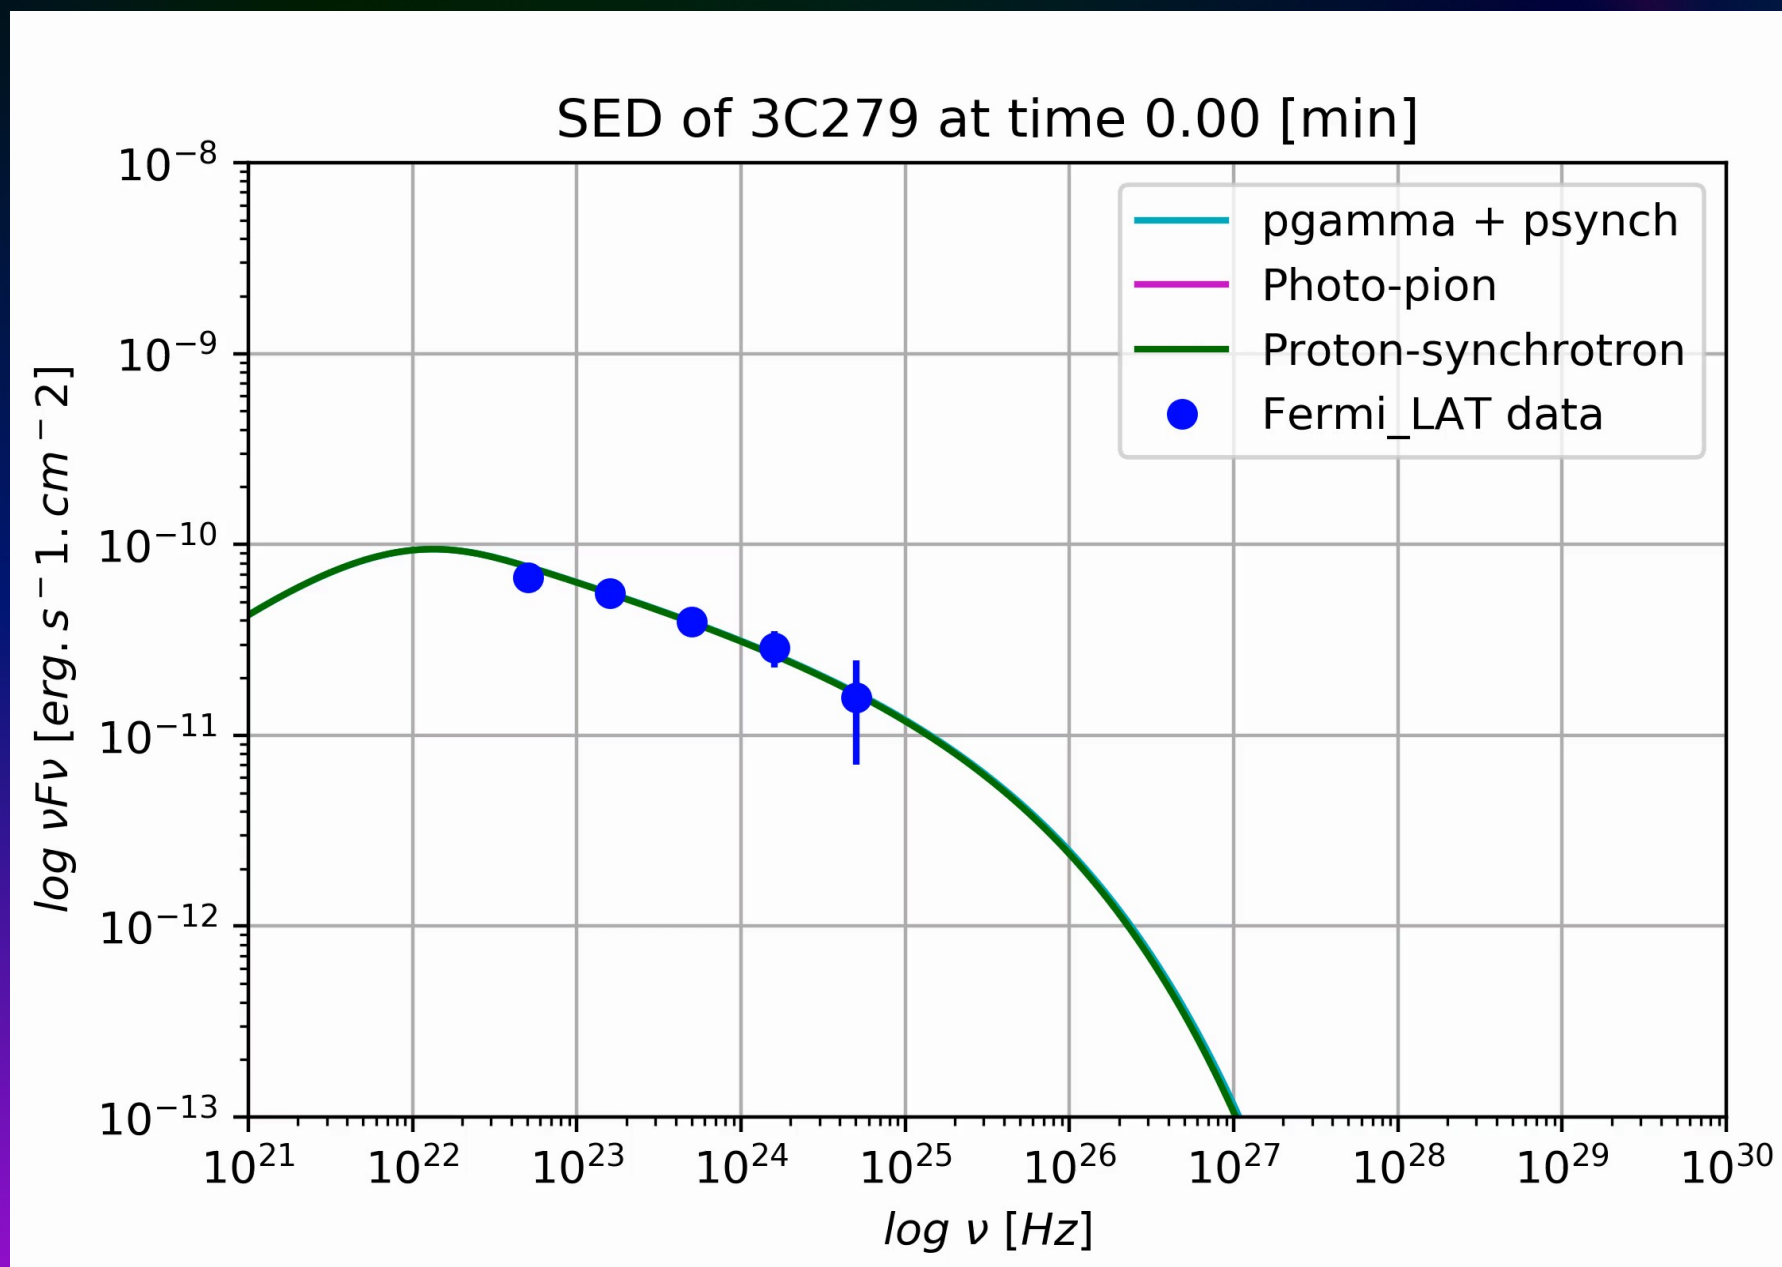

Target photon spectrum

- The target photon spectrum at certain times since the onset of the orphan flare.
- We can see the energy density shoot up after some time passes and then come down again.

3C279 - SEDs

- Cascade development using the semi-analytical treatment of Böttcher et al. (2013).

Lightcurves

Lightcurves of 3C279

- The VHE flare is represented by the model flux at 100 GeV.
- There is a flare of a factor of ~ 2 in flux at 1 GeV.
- The model predicts a significant flare of about 30 min duration.
- The observed time differs from the time in the AGN rest frame, because of light-travel-time effects.
- The light-travel-time effect leads to a contraction of the observed time.

$$t_{obs} = \frac{t_{AGN}}{\Gamma^2}$$

Luminosities

For 3C279

Is the jet power proton or Poynting flux dominated?

- Close to equipartition
- Slightly proton dominated
- Jet power is a little bit larger than the Eddington luminosity.
- This can be explained by the fact that the jet is not in a steady state, so the jet power is only larger for the duration of the flare, and then reverts back to a lower value.

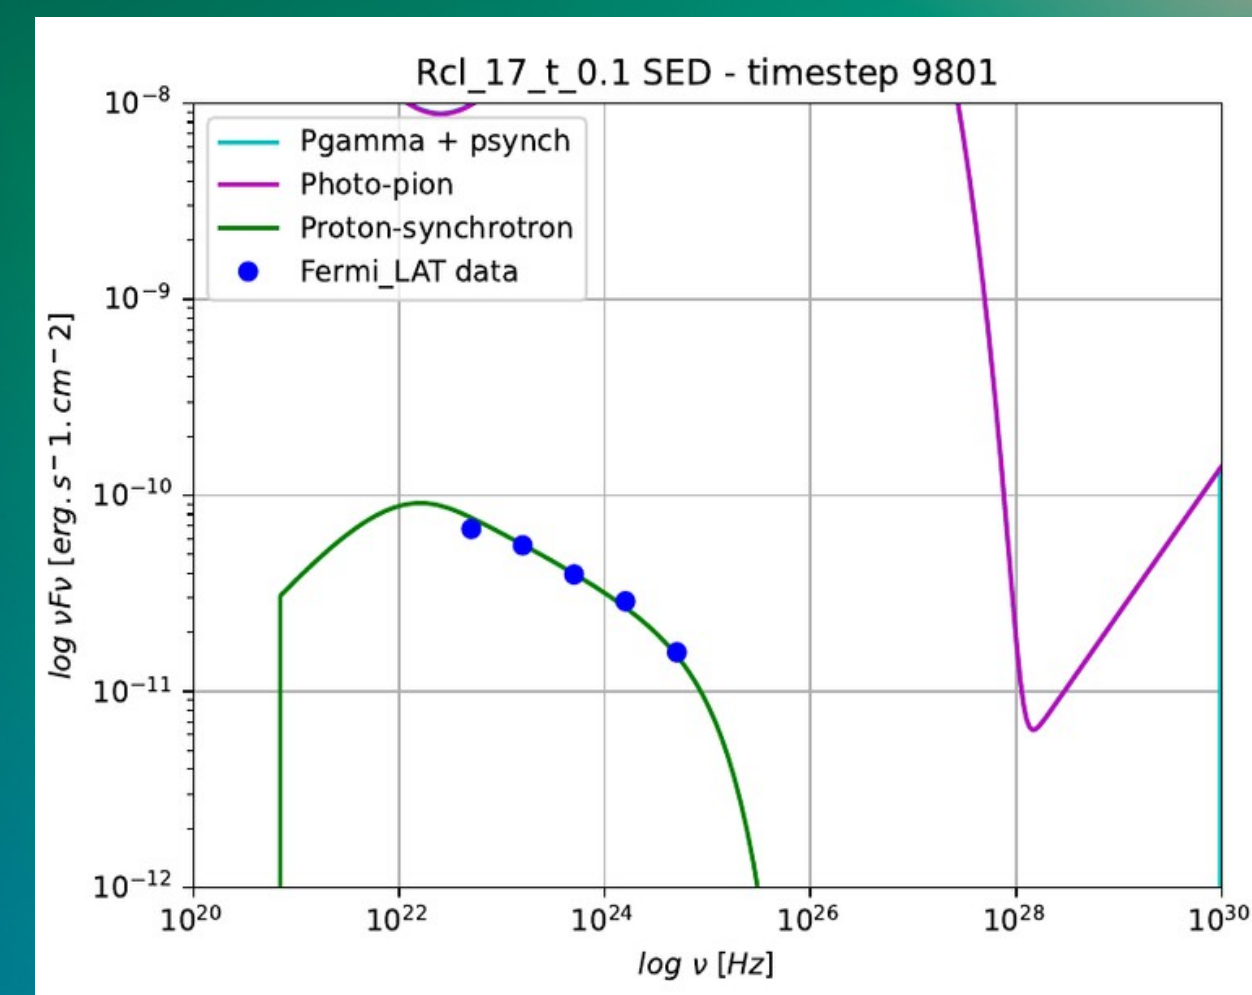

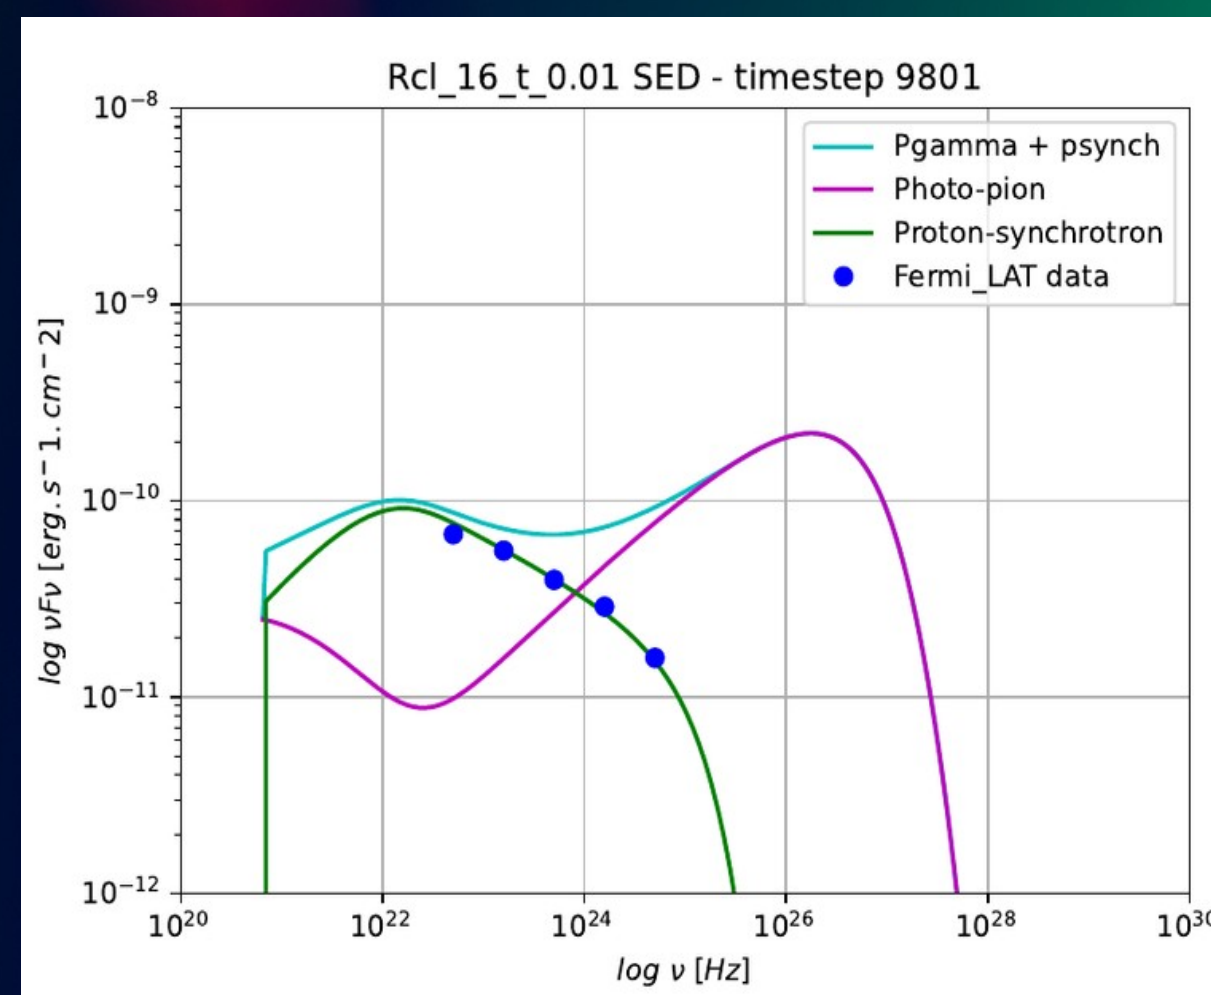

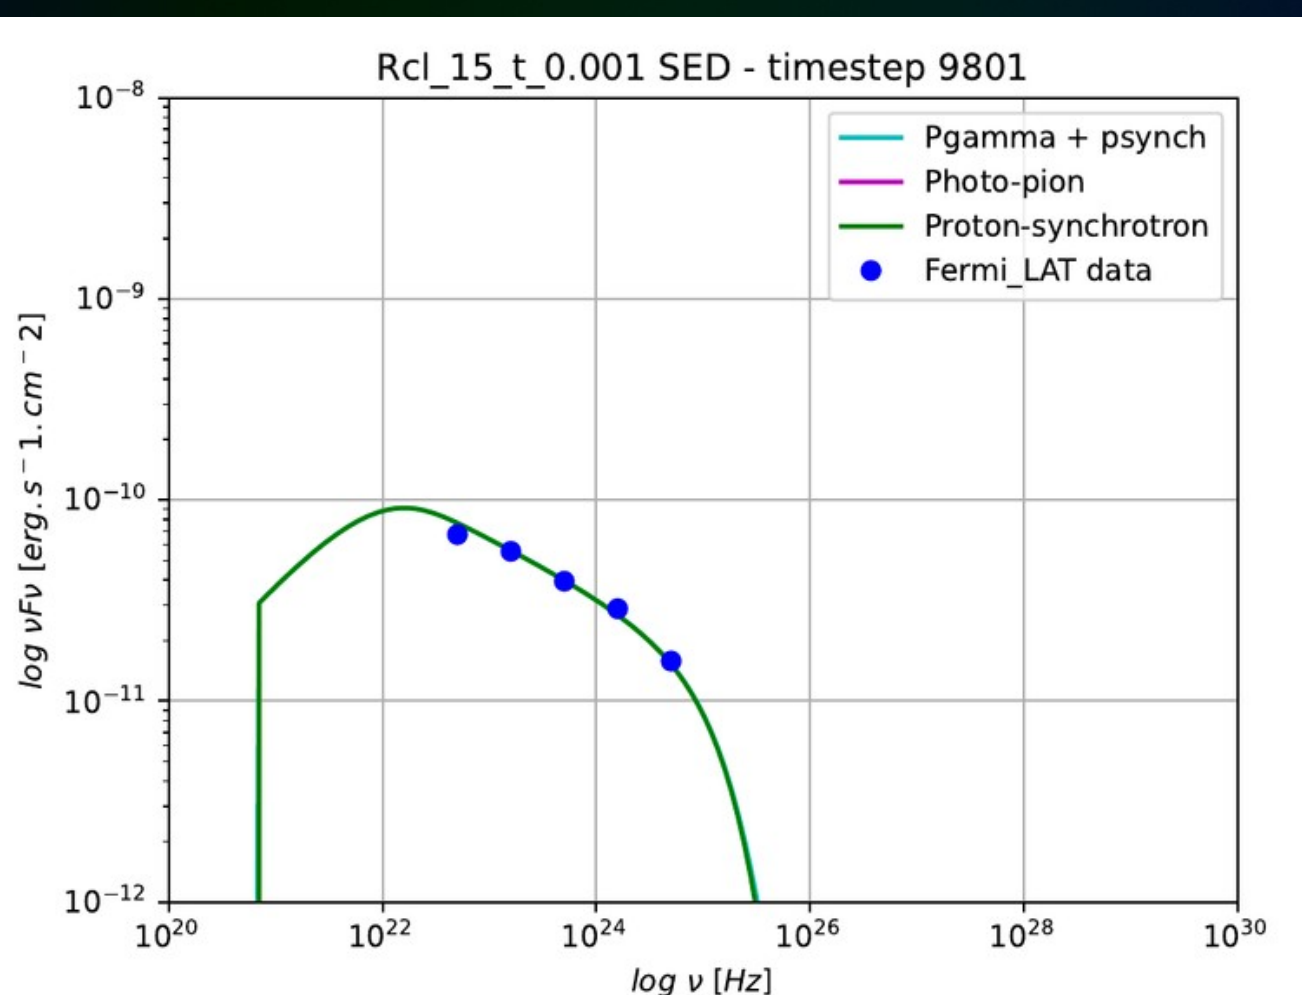

$$L_p \sim \pi R_b^2 c \Gamma^2 \gamma_b^2 m_p c^2 \frac{N_0}{V_b} \sim 2.1 \times 10^{47} \text{ erg.s}^{-1}$$

$$L_B \sim \pi R_b^2 c \Gamma^2 \frac{B^2}{(8\pi)} \sim 9.4 \times 10^{46} \text{ erg.s}^{-1}$$

$$L_{Edd} = 1.3 \times 10^{47} \text{ erg.s}^{-1}$$

$$L_{Sum} \sim 3.04 \times 10^{47} \text{ erg.s}^{-1}$$

Mirror Radius and Tau

R_{cl}	$1 \times 10^{15} \text{ cm}$
τ	0.001

R_{cl}	$1 \times 10^{16} \text{ cm}$
τ	0.01

R_{cl}	$1 \times 10^{17} \text{ cm}$
τ	0.1

- The cloud radius and fraction of reflected photons are varied together.
- If these parameters are too small, the emission is not effective enough.
- If they are too big, the emission is too effective.

Magnetic Field

- The proton Luminosity decreases as the magnetic field increases.
- The Poynting-flux Luminosity increases as the magnetic field does.
- Gammabreak decreases as the magnetic field does.

N_0	3×10^{38}
B	varied
p	1.8
δ	10
R_b	$1 \times 10^{16} \text{ cm}$

R_{cl}	$1 \times 10^{16} \text{ cm}$
τ	0.01

Normalisation

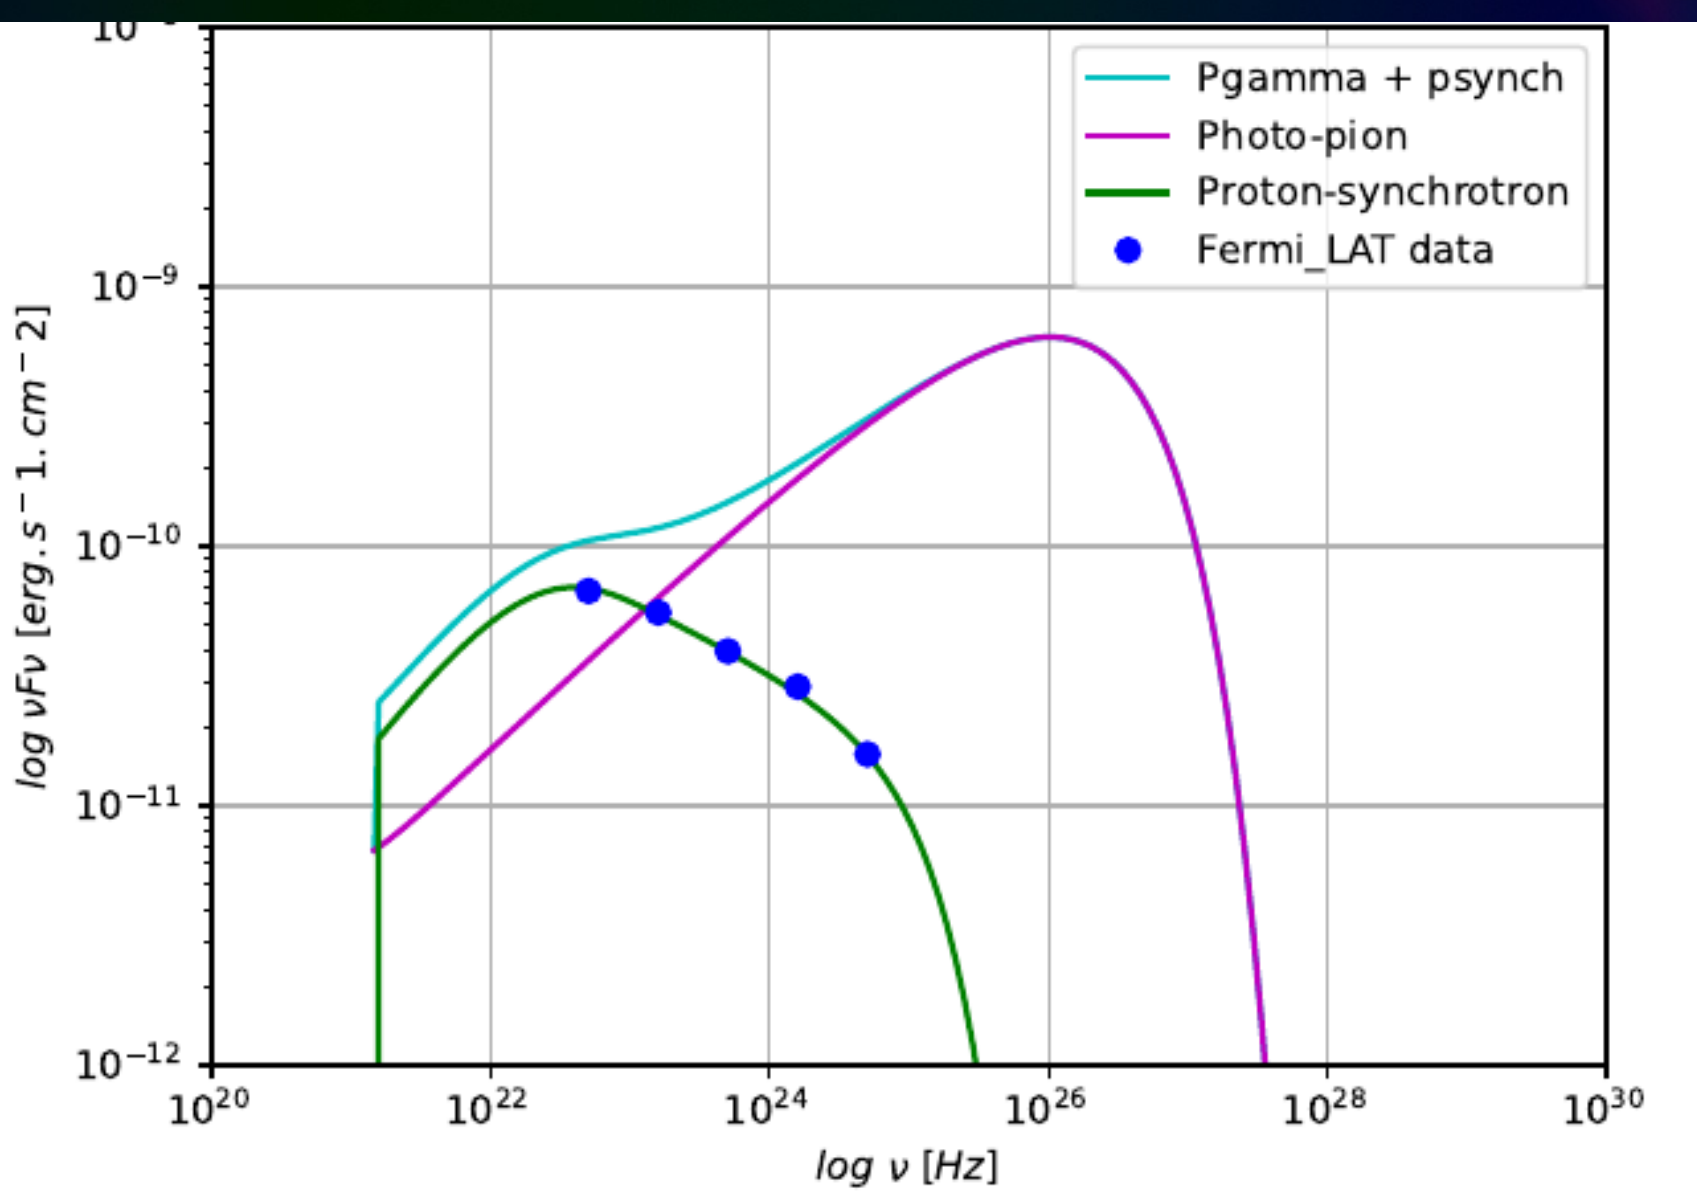

- The proton Luminosity increases as the normalisation increases.
- The Poynting-flux Luminosity stays stable as the normalisation is varied.
- Gammabreak stays stable as the normalisation varies.

R_{cl}	$1 \times 10^{16} \text{ cm}$
τ	0.01

N_0	varied
B	50 G
p	1.8
δ	10
R_b	$1 \times 10^{16} \text{ cm}$

Results

N_0	7.75×10^{37}
B	10 G
p	1.5
δ	22.5
R_b	3×10^{16}

R_{cl}	$1 \times 10^{16} \text{ cm}$
τ	0.01

$$L_{Sum} \sim 2.8 \times 10^{47} \text{ erg.s}^{-1}$$

- Doppler factor and consequently the Lorentz factor was increased
- Magnetic field was decreased and the Normalisation slightly increased
- Emission is too effective
- Jet power decreased slightly

Results

N_0	3×10^{38}
B	53 G
p	1.8
δ	10
R_b	1×10^{16}

R_{cl}	$1 \times 10^{16} \text{ cm}$
τ	0.01

$$L_{Sum} \sim 2.9 \times 10^{47} \text{ erg.s}^{-1}$$

- Radius of the emission region was decreased
- Magnetic field was halved
- Emission is what we expect
- Jet power decreased slightly

Summary

Main take-away: Sub-Eddington luminosities were not found

Summary

- The synchrotron mirror scenario induces a dense enough target photon field.
- This model does predict a moderate flare in Fermi-LAT, but with a much smaller amplitude than that of the VHE flare.
- This suggests that protons are accelerated to ultra-relativistic energies.
- The flare duration is predicted to be about half an hour long, the runtime of one H.E.S.S. observational run.
- Fermi-LAT typically needs longer integration times than half an hour to get a significant detection of 3C279, which could explain why no flare was seen in the Fermi-LAT light curve.

Future work

- Do another parameter study to see if the jet power can be less than the Eddington luminosity. For example, the fraction of reflected photons and cloud radius can be varied independently.
- A comparative study of different models.
 - Multi-zone
 - Combined lepto-hadronic
 - Spine-sheath models.
- Search for neutrino signatures and emission.
- Detection of neutrino emission will also test the models.
- Testing the hadronic synchrotron mirror model on other orphan flares.

谢谢 Thank you

Feel free to ask if you have any questions.

Appendix

Motivation

- Leptonic fit - Redline
- Lepto-Hadronic fit - Greenline
- Electron synchrotron radiation - Component 1
- Proton synchrotron radiation - Component 2
- Photo-Pion Production - Component 3
- We investigate if the photo-pion component can be able to produce the VHE flare.

The Modelling Process

The programming steps:

- Get the parameters describing the relativistic proton population from a proton synchrotron fit to the Fermi-LAT gamma-ray spectrum.
- Numerical evaluation of the target photon field as a function of time.
- Pion production and pion-decay products.
- Calculate the $\gamma\gamma$ -opacity.
- Calculate the resulting electromagnetic cascades to find the emerging SED.

Feasibility of the mirror model

Will the mirror model actually work?

- Semi-analytical approach
- Target photon density for photo-pion production calculated from basic principles.
- The expression for the energy density of the reflected synchrotron radiation:

$$\langle u'_{R,sy}(t_1) \rangle = \frac{4\Gamma^6 \nu F_\nu(sy) d_L^2 \tau R_{cl}^2}{3(R_m - R_b)} \int_0^{\frac{R_m - R_b}{\beta c}} \frac{dt_1}{(R_m - \beta c t_1)^2 (R_m - \frac{\beta c t_1}{2})^2}$$

- A standard integral was used to solve the integrand.
- After simplification a new expression is found where $x_f = \alpha - t_f$ is the time for photo-pion interactions to take place.
- α is the time it takes the blob to move to the centre of the cloud.
- t_f is the total integration time.

$$\langle u'_{R,sy} \rangle = \frac{4\Gamma^6 \nu F_\nu(sy) d_L^2 \tau R_{cl}^2}{3(R_m - R_b)} \left(\frac{4}{(\beta c)^4} \left[\frac{1}{\alpha^2 x_f} + \frac{2}{\alpha^3} \ln \left(\frac{t_f}{2x_f} \right) \right] \right)$$

- By substituting in all the variables the predicted target photon density can be found

Target Photon Energy Density

Will the mirror model actually work?

- The required target photon energy density: $280 \text{ erg}\cdot\text{cm}^{-3}$.
- Estimated actual target photon energy density for standard parameters: $35.2 \text{ erg}\cdot\text{cm}^{-3}$
- Order of magnitude difference.
- By calculating the Lorentz factor for the relativistic protons at the peak of the GEV Fermi-LAT spectrum using the synchrotron frequency.
- The Lorentz factor is used to calculate the synchrotron cooling rate which is compared to the photon-pion energy loss-rates from which the above calculated density is found.
- Conclusively, the target photon field was dense enough for photo-pion production to take place

Photo-pion production

$$\dot{N}_{\gamma}^{\pi^0}(\epsilon) = \sigma_0 n_0 \frac{c N_0 E_{\Delta}}{2 m_{\pi} c^2 (\alpha + 1)} \times \int_{\max[\epsilon \frac{m_e}{m_{\pi}}, \gamma_b, \frac{E_{\Delta}}{2 \epsilon_2 m_e c^2}]}^{\gamma_{cr, \max}} d\gamma_{\pi} \gamma_{\pi}^{-(2+s)} \left(\max \left[\epsilon_1, \frac{E_{\Delta}}{2 \gamma_{\pi} m_e c^2} \right] - \epsilon_2^{-(\alpha+1)} \right)$$

[BÖTTCHER AND DERMER, 1998]

- Photon number spectra
- Use $\sigma_0 = 2 \times 10^{-28} \text{ cm}^2$, the photo-pion differential cross-section, and $E_{\Delta} = 330 \text{ MeV}$, the energy at the threshold for the delta resonance, to find the number spectra.
- The pions are produced near-threshold energy in the proton's rest frame.
- γ_b represents the minimum Lorentz factor beyond which we have the power-law proton spectrum.

Proton Spectrum

Proton-synchrotron component

Proton-synchrotron component

$$N_p(\gamma_p) = N_0 \gamma_p^{-p}$$

$$N_p(\gamma_p) = N_0 \left(\frac{\gamma_p}{\gamma_b} \right)^{-p_{1,2}} e^{-\frac{\gamma_p}{\gamma_c}}$$

Cascade Development

- The photons from the photo-pion decay products are injected at high energies into the jet and form pair cascades.
- The cascades cause pair production and are responsible for the synchrotron radiation.

$$N_e(\gamma) = \frac{1}{\nu_0 \gamma^2} \int_{\gamma}^{\infty} d\tilde{\gamma} \left\{ Q_e(\tilde{\gamma}) + \dot{N}_e^{\gamma\gamma}(\tilde{\gamma}) - \frac{N_e(\tilde{\gamma})}{t_{esc}} \right\}$$

Specific parameter results

Normalisation varied:

The Eddington Luminosity is: $1.3e+47$
 $n_0=7.75e37$:

The Proton Luminosity: $5.4e+46$

The Poynting-flux Luminosity: $9.4e+46$
 $n_0=9e37$:

The Proton Luminosity: $6.3e+46$

The Poynting-flux Luminosity: $9.4e+46$
 $n_0=1e38$:

The Proton Luminosity: $6.9e+46$

The Poynting-flux Luminosity: $9.4e+46$
 $n_0=3e38$:

The Proton Luminosity: $2e+47$

The Poynting-flux Luminosity: $9.4e+46$
 $n_0=5e38$:

The Proton Luminosity: $3.5e+47$

The Poynting-flux Luminosity: $9.4e+46$

Magnetic field varied:

The Eddington Luminosity is: $1.3e+47$
 $B=1$:

The Proton Luminosity: $1e+49$

The Poynting-flux Luminosity: $3.8e+43$
 $B=25$:

The Proton Luminosity: $4.2e+47$

The Poynting-flux Luminosity: $2.3e+46$
 $B=50$:

The Proton Luminosity: $2.1e+47$

The Poynting-flux Luminosity: $9.4e+46$
 $B=75$:

The Proton Luminosity: $1.4e+47$

The Poynting-flux Luminosity: $2.1e+47$
 $B=100$:

The Proton Luminosity: $1e+47$

The Poynting-flux Luminosity: $3.8e+47$
